Chapter 1

Introduction

The introduction was written pretty long ago, maybe rewrite it to be less specifically tied to the German dataset

The Political Mashup project[1] aims to digitize the world's political proceedings in order to make them easily accessible and searchable. Unfortunately, the published documents are often primarily intended to be human-readable, without the embedded semantic structure required to properly index this data in a digital way. This semantic information is currently recovered using rule-based methods. Since the data gets transcribed by a human typist, compiled to a PDF, and then goes back into an imperfect PDF decompiler, there is a lot of room for minor variations in the output even though the layout of the document itself is consistent. Dealing with this in a rule-based system entails using either broad rules that lead to a larger probability of false positives, or a large amount of narrow rules which can quickly lead to a spaghetti-like mess of special cases and is very fragile to unseen issues.

I propose that by using a small number of manually annotated documents as a dataset, a machine learning algorithm can learn to classify sentences in a way that allows it to segment a document into its constituent parts, while being more robust to noise than its rule-based counterpart. The common ways to do sentence classification (e.g. convolutional neural networks [1] , recurrent neural networks or the simpler bag-of-words models) operate on sentences in a vacuum, considering only their linguistic contents and ignoring any contextual information that might be present. This is to be expected considering that most of the common datasets in this area really *are* just small bits of text in a vacuum; often-used datasets involve Twitter messages or short product reviews. In this case however, the sentences come from a document with a rich structure providing a lot of context. Anecdotally, as a human it is trivial to discern section headers in a document even when the document is in a foreign language; simply the fact that the section

[1] http://search.politicalmashup.nl/about.html

header might be printed in bold and centered rather than left-aligned gives it away. Incorporating this structural data into the learning propose will hopefully increase the performance of the system, either by simply scoring better on the used metrics, or perhaps more indirectly by requiring less data or training time to achieve the same score.

Expand section

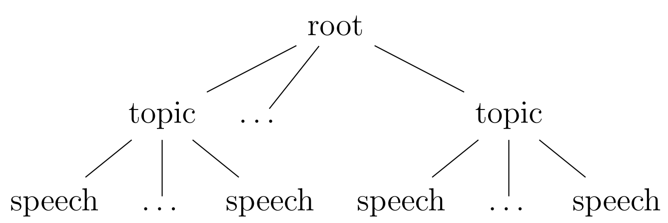
Various forms of convolutional neural networks are commonly used for text classification. The most classical architecture is described by Kim [1], where the input words are tokenized and embedded before passing them to the convolutional neural network. Zhang et al. [4] show that comparable results can be achieved by operating on the character-level rather than the word-level.

In terms of analyzing document structure, Klampfl et al. [2] introduce a method to analyze scientific articles, detecting blocks of text, labeling them (as e.g. section headers, tables or references) and determining the reading order — all in an unsupervised manner. While their approach to block detection forms an integral part of this thesis, the rest is too specifically tied to the format of scientific articles to be applicable in this scenario.

Chapter 3

Problem Statement

The thesis will focus on parliamentary proceedings from the German *Bundestag*. These proceedings are available online as PDF files dating back to 1949, and have used essentially the same document layout and conventions since the start. Semantically, the layout of these documents forms a shallow tree:



Each document consists of a series of topics to discuss, where each topic contains a series of

These PDF files can be converted to an XML representation which retains much of the PDF makeup, or to unstructured plaintext which only preserves newlines. Figure 3.1 shows an excerpt from an arbitrary source PDF file, along with the two possible representations.

The documents are composed of a sequence of topics, each topic having a title and containing a series of speeches. Each of these speeches has a speaker, who in turn have either a party or a role (e.g. minister or president). The task is to parse this information, or as much of it as feasible, from the documents. The dataset, obtained through a rule-based system as described in the introduction, is currently complete dating back to 2005. It features 811 documents, containing 43.252 speeches.

Dr. Norbert Lammert (CDU/CSU):

Herr Alterspräsident, lieber Kollege Riesenhuber, ich nehme die Wahl gerne an.

(Beifall im ganzen Hause – Abgeordnete aller Fraktionen gratulieren dem Präsidenten)

Chapter 4

Approach

The system consists of two separate parts; an unsupervised algorithm for augmenting data, and a supervised algorithm for classifying the data (Figure 4.1). The unsupervised portion attempts to augment the data with additional structural information. It could be considered a preprocessing step, with the choice of parameters acting as a way to inject some amount of domain knowledge into the data. The supervised portion consists of a regular classification algorithm.

Rewrite this and add all the details about how the data is used (sliding window, etc)

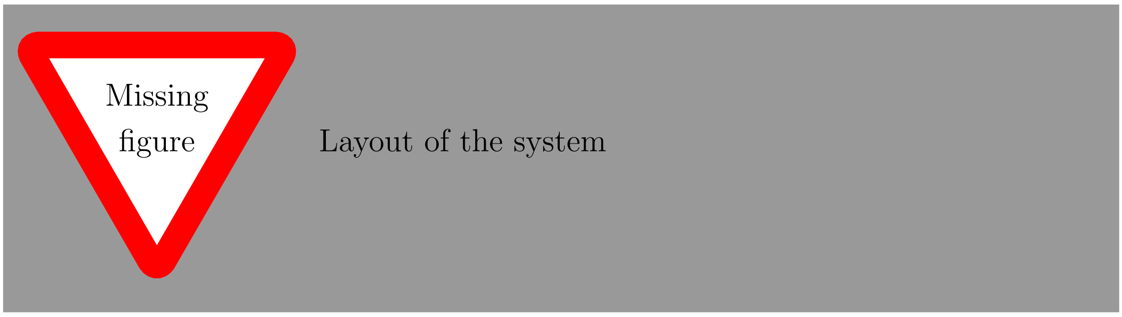

Figure 4.1: A high-level overview of the system

4.1 Unsupervised

The unsupervised algorithm attempts to detect and label blocks of text in the PDF file, as shown in Figure 4.2 for an example). This approach is based on work by Klampfl et al. [2], and consists of two clustering steps:

1. Individual letters are clustered together into blocks of semantically relevant text (e.g. a full paragraph, or a section header).
2. These blocks are labeled by a different clustering algorithm.

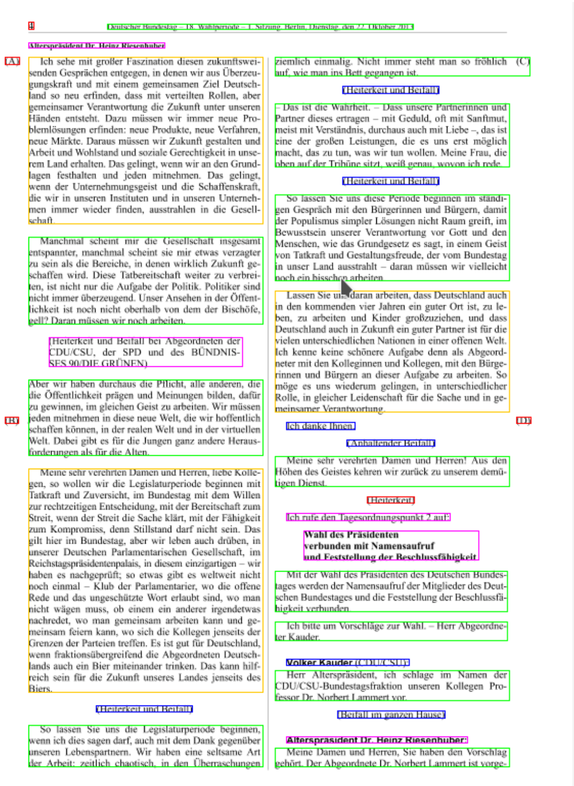

Figure 4.2: An example of clustered blocks of text, blocks with the same outline color belonging to the same cluster.

4.1.1 Hierarchical Agglomerative Clustering

The first step is performed using hierarchical agglomerative clustering (HAC), an unsupervised bottom-up clustering algorithm that constructs a hierarchical tree of clusters (in this context referred to as a *dendrogram*). An example is shown in Figure 4.3. The algorithm gets fed the individual characters present in the PDF files, then iteratively groups the two closests clusters (the initial inputs being regarded as clusters of one element) together until only a single cluster remains. This process involves two parameters:

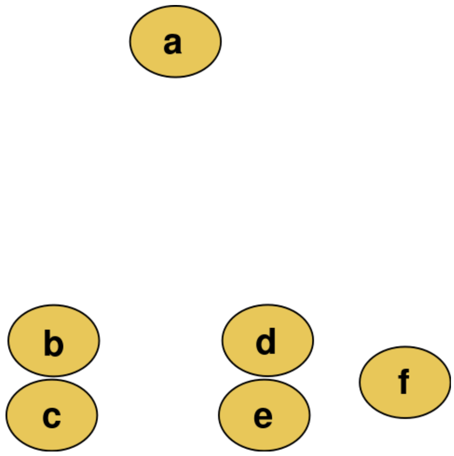
1. The distance function between two characters.

2. The distance function between two groups of characters.

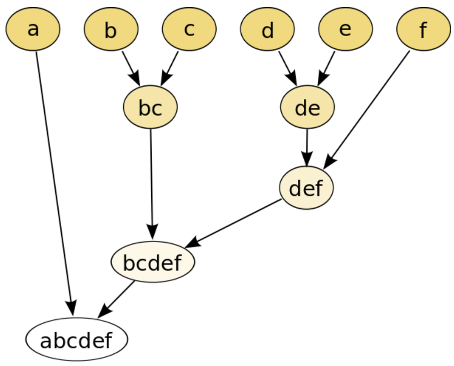
The first parameter is trivially chosen to be the Euclidian distance between the coordinates of the two characters. The second parameter is called the *linkage* and has several common options, the most basic of which are:

- Single-linkage: The distance between groups is based on the closest two elements:
$$d(A, B) = \min\{d(a, b) : a \in A, b \in B\}$$
- Maximum-linkage: The distance between groups is based on the furthest two elements:
$$d(A, B) = \max\{d(a, b) : a \in A, b \in B\}$$
- Average-linkage: The distance between groups is based on the furthest two elements:
$$d(A, B) = \frac{1}{|A||B|} \sum_{a \in A} \sum_{b \in B} d(a, b)$$

As per Klampfl et al. [2], single-linkage clustering performs best for this task due to its tendency to form long thin clusters, mimicking the structure of sentences. As an additional bonus, while the general time complexity for HAC is in $\mathcal{O}(n^3)$, single-linkage clustering can be done in $\mathcal{O}(n^2)$ [3], making it far more usable on realistic datasets.



(a) Before



(b) After

Figure 4.3: An example of hierarical agglomerative clustering.

After the dendrogram is concstructed, the only choice left is at which level to cut the tree to obtain the desired blocks of text. This is left as a parameter to be manually finetuned.

4.1.2 Classical Clustering

The extracted blocks from the previous step are then clustered according to the similarity of their shapes (width and height). This is done using K-means clustering for some chosen K, or with the DBSCAN algorithm.

Either expand this section or just integrate it with the previous subsection.

4.2 Supervised

After the data is augmented by the previously described clustering algorithm, it's fed into a supervised classifier, more specifically a convolutional neural network (CNN). The decision to use a CNN was motivated by both its performanceKim [1] and, for practical reasons, its superior training speed compared to recurrent neural networks.

4.2.1 Convolutional Neural Networks

Explain CNNs

Chapter 5

Results

Todo:

- Difference between running with/without clustering data, vary number of clusters
- CNN vs RNN, probably conclude that RNNs offer no benefit to compensate for the added computational cost
- vary stuff like the embedding size and number of filters
- add tests on older data

Chapter 6

Conclusion

Todo: conclusion
